

CBB 752 - Project 1.3

Extract mutations

```
getMutations <- function(str) {
  (str <- sub(".*", "", str)); (str <- sub(",.*", "", str))
  (str <- sub("\\d+_\\d+_\\d+_\\d+", "", str))
  (from <- sub("->.", "", str));
  (to <- sub(".->", "", str))
  data.frame(from=from, to=to)
}

mutations <- getMutations(x[, "change"])
mutations$syn <- x$syn

table(mutations$from)

##
##  A  C  D  E  F  G  H  I  K  L  M  N  P  Q  R  S  T  V
## 238 85 127 113 87 174 129 225 132 163 157 146 228 137 412 286 296 340
##  W  Y
## 10 48

table(mutations$to)

##
##  *  A  C  D  E  F  G  H  I  K  L  M  N  P  Q  R  S  T
##  3 286 86 148 144 65 175 139 189 102 243 148 139 167 143 315 304 317
##  V  W  Y
## 315 40 65
```

Charge Change

We score each change in the following manner:

```
charge.charge.table = matrix(c(0,1,1,1,0,2,1,2,0), nrow = 3, ncol=3, byrow = TRUE)
row.names(charge.charge.table) <- c("Neutral", "Hydrophilic", "Hydrophobic" )
colnames(charge.charge.table) <- c("Neutral", "Hydrophilic", "Hydrophobic" )
kable(charge.charge.table, caption = "Amino Acid Hydrophobicity Change Table")
```

Table 1: Amino Acid Hydrophobicity Change Table

	Neutral	Hydrophilic	Hydrophobic
Neutral	0	1	1
Hydrophilic	1	0	2
Hydrophobic	1	2	0

Let's calculate the score according to this scoring system

```

# There are many scales for AA hydrophobicity. The following was adapted from:
# http://www.imgt.org/IMGTeducation/Aide-memoire/\_UK/aminoacids/IMGTclasses.html
aa.hydrophobic <- c("A", "C", "I", "L", "M", "F", "W", "V")
aa.hydrophilic <- c("R", "N", "D", "Q", "E", "K")
aa.neutral <- c("G", "H", "P", "S", "T", "Y")
charge_change <- function(values) {
  from <- values[1]; to <- values[2]; cc <- NA
  if(from %in% aa.neutral) {
    if(to %in% aa.neutral) { cc <- charge_change.table["Neutral", "Neutral"] }
    if(to %in% aa.hydrophilic) { cc <- charge_change.table["Neutral", "Hydrophilic"] }
    if(to %in% aa.hydrophobic) { cc <- charge_change.table["Neutral", "Hydrophobic"] }
  }
  if(from %in% aa.hydrophilic) {
    if(to %in% aa.hydrophilic) { cc <- charge_change.table["Hydrophilic", "Hydrophilic"] }
    if(to %in% aa.neutral) { cc <- charge_change.table["Hydrophilic", "Neutral"] }
    if(to %in% aa.hydrophobic) { cc <- charge_change.table["Hydrophilic", "Hydrophobic"] }
  }
  if(from %in% aa.hydrophobic) {
    if(to %in% aa.hydrophobic) { cc <- charge_change.table["Hydrophobic", "Hydrophobic"] }
    if(to %in% aa.neutral) { cc <- charge_change.table["Hydrophobic", "Neutral"] }
    if(to %in% aa.hydrophilic) { cc <- charge_change.table["Hydrophobic", "Hydrophilic"] }
  }
  return(cc)
}

mutations$cc <- apply(mutations, 1, charge_change)

```

Plot of AA change in charge

```

qplot(mutations$cc,
      geom="histogram",
      main="Charge Change Histogram", xlab="",
      border="blue", fill="red")

```

Charge Change Histogram

Size Change

As an estimate for size, we used the average volume of buried residues, calculated from the surface area of the side chain (Richards 1977; Baumann et al. 1989) Adapted from: http://www.proteinsandproteomics.org/content/free/tables_1/table08.pdf

```
aa.sizes <- list("A"=92 , "C"=106, "I"=169, "L"=168, "M"=171, "F"=203,
                "W"=240, "V"=142, "R"=255, "N"=135, "D"=125, "Q"=161,
                "E"=155, "K"=171, "G"=66 , "H"=167, "P"=129, "S"=99 ,
                "T"=122, "Y"=203, "*" =0)
mutations$size <- abs(as.numeric(unlist(aa.sizes[mutations$from])) -
                     as.numeric(unlist(aa.sizes[mutations$to])))
qplot(mutations$size,
      geom="histogram",
      main="Size difference Histogram", xlab="",
      border="blue", fill="red")
```

Size difference Histogram

Blosum 90

```
data("blosum90")
blosum <- function(values) {
  b <- NA
  from <- values[1]; to <- values[2];
  if( from != "*" & to != "*" ) { b <- blosum90[from,to] }
  return(b)
}

mutations$blosum <- apply(mutations, 1, blosum)
qplot(mutations$blosum,
      geom="histogram",
      main="Blosum 90 Histogram", xlab="",
      border="blue", fill="red")
```

Blosum 90 Histogram

GERP Score

```
gerp <- function(str) {  
  tmp <- sub("GERP=", "", str)  
  tmp <- sub(";.*", "", tmp)  
  return(as.numeric(tmp))  
}  
  
mutations$gerp <- gerp(x$GERP)  
  
hist(mutations$gerp, probability = TRUE, las=3,  
      main="GERP Score Histogram", xlab="",  
      border="blue", col="red")
```

GERP Score Histogram

Premature Stop

We have several premature stop cases. Let's see how short is the read compared to the reference.

```
pre.1 <- which(mutations$syn == "prematureStop")
pre <- x[pre.1, c("mutant", "wildtype")]
pre$missing.len <- as.numeric(nchar(pre$wildtype) - regexpr("\\*", pre$mutant))
```

We can see that we have 3 missing nonsense mutations. One with length of 15, and two others with length of 101. We can assume that the longer the deletion is, the more deleterious it is.

Summary Statistics

Let's see what is the frequency of each mutation.

```
mutations.1 <- array()
for(i in 1:nrow(mutations)) {
  m <- paste(mutations$from[i], mutations$to[i], sep="")
  mutations.1 <- c(mutations.1, m)
}
```

```
sort(table(mutations.1))
```

```

```

Deleterious Score (DScore)

We define Dscore as following (for discussion see the writing section)

$$DScore = \alpha Charge + \beta Size + \gamma GERP + \delta Blosun$$

Each one of the coefficients can be determined by the user. We chose for example:

$$\alpha = \beta = \gamma = \delta = 1$$

```
coeff <- list(c=1, s=1, b=1, g=1) # This we can get as user input
mutations$score <- coeff$c*mutations$cc + coeff$s*mutations$size +
  coeff$b*mutations$blosun + coeff$g*mutations$gerp
m <- which.max(mutations$score)
print(paste("The most deleterious mutations is:", x$loc[m]))
```

```
## [1] "The most deleterious mutations is: chr3:183975365:C:T"
```
